Homochiral recognition by non-covalent interactions is a rather common phenomenon in helical structures.[1] However, this asymmetric trend has been hardly exploited for the formation of covalent bonds between helicenes.[2] Herein, we report the oxidative coupling of the cationic [4]helicenes **1,** which proceeds with a quasi exclusive homochiral recognition (96% selectivity) to yield chiral (racemic) dimers of type **2**. The lack of *meso* isomers is established by HRMS cross-over experiments. Moreover, this reaction is highly atroposelective forming preferentially ($R_a$,$M$,$M$)-**2a** over ($S_a$,$M$,$M$)-**2b** (and enantiomers) (ratio 90:10). The interconversion barrier from **2a** to **2b** is 26.4 kcal/mol at 60 °C in dmso-$d_6$. Strong chiroptical properties are observed, for both **2a** and **2b**, in the red visible region.
