We report the palladium-catalyzed transformation of CO_2 and H_2 to formate at low pressure (2 bar) and ambient temperature in presence of a base. Palladium-hydride complex **1** was synthesized from its chloride precursor with NaH in THF. The 1 H-NMR spectrum shows a triplet at δ -3.40 ppm with a 2 J_{P-H} coupling constant of 20.7 Hz. The formate complex **2** was obtained by exposing **1** to CO_2 as indicated by a triplet signal in the 1 H-NMR spectrum at δ 9.18 ppm with a 4 J_{P-H} coupling constant of 1.7 Hz and a singlet signal at δ 166.6 ppm in the broadband decoupled 13 C-NMR spectrum. After degassing of complex **2**, addition of a base and application of a H_2 -atmosphere regenerated the hydride complex **1**, thus completing the proposed catalytic cycle. The formation of formic acid was confirmed by NMR and headspace GC-MS measurements after treatment with HCl.
