Ionic Liquids (IL) are organic salts with melting temperature typically below 100 °C. The unique properties of ionic liquids such as their excellent chemical and thermal stabilities (e.g. tetraethylammonium tetrafluoroborate can be heated up to 745°C [1]), their low vapor pressure, their important ionic conductivity makes them interesting compounds in material science and especially in thermoelectric generators (TEGs) for medical, pharma or electronic applications [2].

In our work, we describe the synthesis, physical, and thermo-electrochemical characterization of novel IL for application in thermoelectric generators (TEGs). We discuss the optimization of the chemical structure of IL regarding their thermoelectric properties via a structure-activity relationship approach [3]. The thermal stability of ionic liquids was investigated using thermogravimetric analysis in order to do a scale up of the synthesis of these ionic liquids.
