<sup>1</sup>ETH Zurich

Over the past decades, the hydrogenation of CO<sub>2</sub> to more valuable products such as formic acid or methanol has been highly emphasized in the academic field because of the continuous increase of CO<sub>2</sub> in the earth's atmosphere. The challenge of converting CO<sub>2</sub> results mainly from its considerable Gibbs free energy ( $\Delta G^\circ = -394.4$  kJ/mol). Therefore active co-reactants and/or catalysts are usually needed. Formic acid, one of the CO<sub>2</sub> hydrogenation derivatives, is an efficient hydrogen carrier and has great potential to be applied in fuel cells. Nowadays various efficient homogeneous catalytic systems have been developed to convert CO<sub>2</sub> to formic acid, such as the iridium complexes with PNP pincer-type<sup>1,2</sup> and bipyridine-type ligands<sup>3</sup> or<sup>4</sup> ruthenium complexes with N-heterocyclic carbenes.<sup>4</sup> However, the above-mentioned homogeneous catalysts were only applied in batch reactors, which are less favored in industrial continuous processes, and efficient well-defined immobilized catalysts are still sparse in CO<sub>2</sub> hydrogenation. Here, we aim at synthesizing new immobilized catalysts, which are supported on well-defined silica-based hybrid materials or synthetic polymers, and applying them in a continuous CO<sub>2</sub> hydrogenation process.
